Abstract. Abstract The neurons of the cochlear ganglion transmit acoustic information between the inner ear and the brain. These placodally derived neurons must produce a topographically precise pattern of connections in both the inner ear and the brain. In this review, we consider the current state of knowledge concerning the development of these neurons, their peripheral and central connections, and their influences on peripheral and central target cells.

These neuroblasts form the primary neurons of the auditory and vestibular path-ways, the cochlear and vestibular ganglia, linking the inner ear and the central nervous system (CNS). Their

development and the integrity of their descendants in the mature animal are essential for processing of acoustic and vestibular infor-mation.

The neurons of the primary auditory cortex can be considered to have receptive fields covering a range of auditory frequencies and have selective responses to harmonic pitches. Neurons integrating information from the two ears have receptive fields covering a particular region of auditory space.

Early investigations of the neural representation of the twitter call in marmosets established several important findings. First, the responses of marmoset primary auditory cortex neurons tended to lock to the temporal envelope of the call (Figure 3) (Wang et al. 1995). Because the frequency-modulated (FM) sweep in each phrase of the twitter call spans many frequencies, neurons with a range of center frequencies responded to each phrase, and as such, there is a distributed population ...

Primary auditory neurons carry action potentials from the cochlea into the transmission pathway shown in the adjacent image. Multiple relay stations act as integration and processing centers. The signals reach the first level of cortical processing at the primary auditory cortex (A1), in the superior temporal gyrus of the temporal lobe . [5]

The primary auditory cortex (Fig. 6B; Brodmann area 41) is located along the upper bank of the superior temporal gyrus, within the lateral sulcus on two gyri known as Heschl's gyri. Similar to other sensory cortices, the primary auditory cortex is organized in columns, such that each column of cells responds maximally to an acoustic stimulus of a specific frequency.

Layer 4 (L4) of primary auditory cortex (A1) receives a tonotopically organized projection from the medial geniculate nucleus of the thalamus. However, individual neurons in A1 respond to a wider range of sound frequencies than would be predicted by their thalamic input, which suggests the existence of cross-frequency intracortical networks.

The difference between these two percentage changes was insignificant ($p < 0.05$). On the other hand, electric stimulation of the MGBm neurons with a Q-30 dB value < 6.0 and of the MGB neurons with a Q-30 dB between 6.0 and 9.0 broadened 17 cortical frequency-threshold curves without BF shifts (open circles).

High-precision temporal coding in the mammalian auditory brainstem is essential for sound source localization [3, 4], but there is also general agreement that much of this precision is lost by the time the signal reaches the primary auditory cortex (A1), which instead for most mammals appears to rely primarily upon an unsynchronized rate-coding strategy to encode whole sounds and sequences [1 ...

However, most studies of processing in the primary auditory cortex (A1) have viewed neurons as independent filters; little is known about how coordinated A1 neuronal activity is expressed throughout cortical columns and how it might enhance the processing of auditory information.
