The W and Z bosons are together known as the weak or more generally as the intermediate vector bosons. These elementary particles mediate the weak interaction; the respective symbols are W⁺ W⁻, and Z⁰. The W[±] bosons have either a positive or negative electric charge of 1 elementary charge and are each other's antiparticles. The Z⁰ boson is electrically neutral and is its own antiparticle.

If a non-zero complex number z is given in polar form as $z = re^{i\theta}$ (r and θ real numbers, with $r > 0$), then $w = \ln(r) + i\theta$ is one logarithm of z . Since $z = re^{i(\theta + 2k\pi)}$ exactly for all integer k , adding integer multiples of 2π to the argument θ gives all the numbers that are logarithms of z : [1]

History. The basic idea now known as the Z-transform was known to Laplace, and it was re-introduced in 1947 by W. Hurewicz and others as a way to treat sampled-data control systems used with radar. It gives a tractable way to solve linear, constant-coefficient difference equations. It was later dubbed "the z-transform" by Ragazzini and Zadeh in the sampled-data control group at Columbia ...

A linear transformation is a function from one vector space to another that respects the underlying (linear) structure of each vector space. A linear transformation is also known as a linear operator or map. The range of the transformation may be the same as the domain, and when that happens, the transformation is known as an endomorphism or, if invertible, an automorphism.
