sion of vibrations/sound through different materials such as metals and polymers. Viscoelasticity and glass transition are two important factors which influence the vibration damping of polymers. Among polymers, rubbers exhibit greater damping capability compared to plastics. Rubbers reduce vibration and sound whereas metals radiate sound.

When sound hits the material, the damping product stretches or extends (hence, extensional damping) and then compresses, converting the noise and vibrational energy into heat. Free layer damping controls vibration and noise in products with surfaces

that are at or near resonance and is best for lightweight structures. This is because free layer damping does add a significant amount of weight to your structure, meaning that it is not ideal for applications where limiting weight is a concern.

The studies of sound and vibration are closely related. Sound, or pressure waves, are generated by vibrating structures (e.g. vocal cords); these pressure waves can also induce the vibration of structures (e.g. ear drum). Hence, attempts to reduce noise are often related to issues of vibration.
