### Solution To Stability Of Structures

The number of external reactions is often the simplest means to determine the stability of a structure. They must be greater than the number of equations available for the structure to remain in static equilibrium. The number of equations for two-dimensional (planar) structures (e.g., 2D trusses and 2D frames) is three (i.e.,  $F_x = 0$ ,  $F_y = 0$ ,  $M$

It was very evident that the less structure there was there the more unstable the tower. A single tower collapsed within a single swing of the lemon. The double sized tower took two swings, in either orientation. When reinforced all the way through it still only lasted 2 swings. The Quadruple tower lasted 6 swings. We also then started talking about making things stronger without using as many ...

It is necessary to establish stability criteria in order to answer the question of whether a structure is in stable equilibrium under a given set of loadings. If upon releasing the structure from its virtually displaced state the structure returns to its previous

configuration, then the structure is in stable equilibrium.

9.1 Tre tz Condition for Stability In 1933 the German scientist Erich Tre tz proposed the energy criterion for the determination of the stability of elastic structures. We shall explain this criterion on a simple example of a one-degree-of-freedom structure. Consider a rigid column free at one end and hinged at the other.

INTERNAL STABILITY OF TRUSS: Internal stability of truss depends upon the arrangements of members and joints as.  
 \* If  $m + r = 2j$  internally stable \* If  $m + r < 2j$  internally unstable \* If  $m + r > 2j$  indeterminate. Where  $m$  = number of members,  $j$  = number of joints,  $R$  = number of unknown reactions. For complete stability the should be both internally and externally stable.

Stability, in mathematics, condition in which a slight disturbance in a system does not produce too disrupting an effect on that system. In terms of the solution of a differential equation, a function  $f(x)$  is said to be stable if any other solution of the equation that starts out sufficiently close to it when  $x = 0$  remains close to it for succeeding values of  $x$ .
