Oxidative folding was approximately tenfold slower on ER57 knockdown; however, minimal disruption was observed for assembly of the peptide-loading complex components as well as ER to Golgi transport. In contrast, studies with the ERp57 $-/-$ cell line found that MHC class I heavy chain folding was unaffected [107]. Formation of the peptide-loading complex occurred; however, its stability was impaired and led to decreased antigen presentation.

During oxidative folding of peptides, disulfide bonds are formed by multistep, reversible thiol-disulfide exchange reactions. Prior studies suggested that oxidation yield may be influenced by the GSH:GSSG ratio, which facilitates thiol-disulfide exchange during the oxidation process [35,36]. We systematically evaluated the effect of different ratios of GSH and GSSG.

One recent advancement in the oxidative folding methods is the use of polymer-supported oxidation. 17–19 Simplifying oxidative folding by replacing disulfide bridges with isosteric diselenide bridges 20–27 is another attractive strategy, but it has yet to be widely used

by peptide chemists. The advantage of the selenopeptide technology is the redox-favored formation of the diselenide bridge compared to presence of disulfide bridges, ensuring the regioselective formation of cross-links.
