Naive Bayesian Rough Sets 3 fact, uses a threshold of 0 on the dierence between the a posteriori and the a priori probabilities, or a threshold of 1 on the likelihood ration; the rough Bayesian model uses a pair of arbitrary threshold values. However, the latter model does not address the problem of how to setting the threshold values.

A naive Bayesian classifier is a probabilistic classifier based on Bayesian decision theory with naive independence assumptions, which is often used for ranking or constructing a binary classifier. The theory of rough sets provides a ternary classification method by approximating a set into positive, negative and boundary regions based on an equivalence relation on the universe.

The naive Bayesian classifier model is based on the Bayesian rule and works as follows. Assume input space $X \subseteq R^n$ is the set of n -dimension vectors, and output space is the set of class tags $Y = \{c_1, c_2, \dots, c_k\}$. Feature vectors $x \in X$ are the inputs whereas class labels $y \in Y$ are the outputs.

Naive Bayesian classifier is widely used in machine learning because it is fast and easy to be implemented. Rennie et al. show that its performance is competitive with the state-of-the-art models like SVM while the latter has too many parameters to decide. Therefore, we choose the naive Bayesian classifier as the core of fine tuning.

Naive Bayesian classifier (NBC) is a simple and effective classification model, but its condition independence assumption is often violated in reality and makes it perform poorly. In our study, we attempt to improve the NBC model through the way of attribute selection based on rough set.
