A new, synthetic material changes colour when it is twisted or stretched. Such a smart material could be used for any number of applications. We take a look. In nature, many colours are derived from pigments. Some of the most intense, such as those found in opals, feathers and wings, are due to the innate surface structure. Natural opals are formed when water evaporates, leaving behind silica spheres that settle into layers.

Some materials signal temperature changes even more dramatically by changing color as they get hotter or colder: we say they're thermochromic (from the Greek words *thermos* = heat, *chroma* = color). Materials like this are the secret ingredient in everything from mood rings and forehead strip thermometers to battery testers and coffee cups that change color when you pour hot drinks into them.

Color-changing fabrics are another goal for electrochromics. Chameleonic materials could be used for adaptive camouflage or wearable displays, or simply for fashion. Because electrochromic polymers can be put into solution, they can be stenciled onto flexible fabric substrates, and low power requirements mean that flexible electrodes could be used to switch the colors.

Bis(diethylammonium) tetrachlorocuprate (II) ($[(CH_3CH_2)_2NH_2]_2[CuCl_4]$) is a bright green solid material, which at 52–53 °C reversibly changes color to yellow. The color change is caused by relaxation of the hydrogen bonds and subsequent change of geometry of the copper-chlorine complex from planar to deformed tetrahedral, with appropriate change of arrangement of the copper atom's d-orbitals.
