Snow on the ground tends to become increasingly dense, and, where it survives spring and summer melting for years, it may turn into ice and form a

glacier. On hillsides when temperature changes reduce the coherence of snow particles in the snow cover, gravity and viscosity may overcome friction, causing snow slides and avalanches.

Congelation ice forms as water freezes on the bottom of the ice cover, and the latent heat of crystallization is conducted upward through the ice and snow to the atmosphere. Formation of sea ice on the bottom of an established sea ice cover in the form of platelets, which coalesces to form solid ice, is also represented by congelation ice. Its growth rate is proportional to the rate at which energy is transferred from the bottom surface of the ice layer to the air above.
