A retinal dose of AAV could contain 300-500 billion capsids. Not all capsids will make it into the nucleus of the retinal cell — where they need to be to work — and some capsids don’t have cargo. That’s why so many capsids need to be in the bleb for enough therapeutic gene to get into the retinal cells.

Second, retinal cells do not proliferate after birth. This is important as a single injection could potentially offer life-long expression of the therapeutic protein. Third, a number of animal models are available for inherited retinal diseases, which is instrumental for safe and efficient drug development.

Retina Degeneration - an overview | ScienceDirect Topics

Summary. Biallelic mutations in the RPE65 gene are associated with inherited retinal degenerations/dystrophies (IRD) and disrupt the visual cycle, leading to loss of vision. A new adenoviral vector-based gene therapy surgically delivered to retinal cells provides normal human RPE65 protein that can restore the visual cycle and some vision.

All eyes on Retinal Gene Therapy

Inherited retinal dystrophies are a group of eye diseases caused by gene mutations which result in the gradual degeneration of the light sensitive cells (photoreceptor cells) on the back of the eye (the retina). The RPE65 gene provides instructions for making a protein that is essential for normal vision. RPE65-mediated inherited retinal dystrophies are rare and serious.

The gene, which is called RPE65, is injected into the eye, under the retina, in an operating room procedure performed by Dr. Maguire. The gene enters retinal cells because it is packaged into a safe virus called adeno-associated virus (AAV).
