Pulse Amplitude Modulation (PAM) Pulse amplitude modulation is a type of modulation in which the amplitudes of regularly spaced

rectangular pulses vary according to instantaneous value of the modulating or message signal. In fact, the pulses in a PAM signal may be of flat top type or natural type or ideal type. Out of all the three pulse amplitude modulation methods, the flat top PAM is most ...

We have discussed in earlier sessions about the parameters used in Amplitude Modulation. To determine the parameters, each one has its own formula. By using those formulas, we can find out the respective parameter values. In this chapter, few problems are solved based on concept of amplitude modulation in order to understand the concept easily.

Use a highpass filter to remove the lower sideband signal; this process is single sideband (SSB) modulation. However, by removing one of the sidebands we lose some of the original power of the modulated signal. To maximize the power transmitted, transmit both the lower and the upper sideband. This process is double sideband (DSB) modulation. The following figure illustrates DSB.

Figure 1 PAM4 doubles the number of bits in serial data transmissions by increasing the number of levels of pulse-amplitude modulation, but does so at the cost of noise susceptibility.. If we look at that NRZ signal as an eye diagram, it will have a bit period, T , and amplitude, A . The required bandwidth for this signal is related to the bit period ($1/T$).

of modulation used to transmit information, such as an audio signal, by radio waves. A refinement of amplitude modulation, it

uses transmitter power and bandwidth more efficiently. Amplitude modulation produces an output signal the bandwidth of which is twice the maximum ...
