The identity of a subgroup is the identity of the group: if G is a group with identity e , and H is a subgroup of G with identity e_H , then $e_H = e$. The inverse of an element in a subgroup is the inverse of the element in the group: if H is a subgroup of a group G , and a and b are elements of H such that $ab = ba = e_H$, then $ab = ba = e$.

Subgroup structure viewed as symmetric group Classification based on partition given by orbit sizes. For any subgroup of S_n , the natural action on $\{1, \dots, n\}$ induces a partition of the set into orbits, which in turn induces an unordered integer partition of the number n . Below, we classify this information for the subgroups.

A hypergraph is a set endowed with a set of subsets. The hypergraph of subgroups is the data of the set of subgroups, and therefore to say that groups G, H have isomorphic hypergraphs of subgroups means that there's a bijection $f: G \rightarrow H$ such that for every subset $A \subseteq G$, $f(A)$ is a subgroup of H if and only if A is a subgroup of G .

In mathematics, the closed-subgroup theorem is a theorem in the theory of Lie groups. It states that if H is a closed subgroup of a Lie group G , then H is an embedded Lie group with the smooth structure agreeing with the embedding. One of several results known as Cartan's theorem, it was first published in 1930 by Élie Cartan, who was inspired by John von Neumann's 1929 proof of a special case for groups of linear transformations.

The dihedral group Dih_4 has ten subgroups, counting itself and the trivial subgroup. Five of the eight group elements generate subgroups of order two, and the other two non-identity elements both generate the same cyclic subgroup of order four. In addition, there are two subgroups of the form $\mathbb{Z}_2 \times \mathbb{Z}_2$, generated by pairs of order-two elements. The lattice formed by these ten subgroups is shown in the illustration.
