Seismic microzonation is defined as the process of subdividing a
potential seismic or earthquake prone area into zones with
respect to some geological and geophysical characteristics of the
sites such as ground shaking, liquefaction susceptibility, landslide
and rock fall hazard, earthquake-related flooding, so that seismic

hazards at different locations within the area can correctly be identified.

This study focuses on two weak points of the present procedure to carry out microzoning study in near-field areas: (1) the Ground Motion Prediction Equations (GMPEs), commonly used in the reference seismic hazard (RSH) assessment; (2) the ambient noise measurements to define the natural frequency of the near surface soils and the bedrock depth.
