The ratio between lift and aircraft weight is called the load factor n , where, i.e. $n = 0$ for free fall, $n = 1$ for level flight, $n > 1$ to pull out of a dive and $n < 1$ to pull out of a climb. The overall load spectrum of an aircraft is captured graphically by so called velocity – load factor (V - n) curves.

Aerodynamics, from Greek ἀήρ aero (air) + δυναμική (dynamics), is the study of motion of air, particularly when affected by a solid object, such as an airplane wing. It is a sub-field of fluid dynamics and gas dynamics, and many aspects of aerodynamics theory are common to these fields. The term aerodynamics is often used synonymously with gas dynamics, the difference being that ...

If all aspects of an aircraft are very rigid, calculating the aerodynamic loads using CFD is sufficient. This usually isn't the case. Like with the linear static case, the load can change and reduce the stiffness of the structure, causing additional deformation and additional loading.
