Heterolytic Fragmentation Of Organic Molecules

Heterolytic fragmentation is a widespread but neglected class of organic reactions. It involves the regulated cleavage of molecules containing certain combinations of atoms such as carbon, oxygen, nitrogen, sulfur, phosphorus, silicon, boron and halogens. Fragmentation reactions are useful in degradation and structure elucidation, some are also of preparative value.

The study of heterolytic fragmentations contributes heavily to the understanding of heteroelectronic effects in organic chemistry. In addition, sometimes the most expedient way to incorporate (in a synthesis) a particular framework or array of functional groups uses a fragmentation pathway, or a fragmentation may be a mandatory step in determining a structure.

Homolytic vs. Heterolytic Fragmentation. Most organic transformations involve the movement of electron pairs (heterolytic reactions). There are a few important addition reactions, however, in which the electron reconfiguration involves the movement of single electrons. Whereas heterolytic bond cleavage leads to ion pairs, homolytic bond cleavage results in unpaired electrons – or free radicals.

Homolytic vs. Heterolytic Fragmentation

In chemistry, heterolysis or heterolytic fission (from Greek ἕτερος, heteros, "different", and λύσις, lysis, "loosening") is the process of cleaving a covalent bond where one previously bonded species takes both original bonding electrons from the other species. During heterolytic bond cleavage of a neutral molecule, a cation and an anion will be generated.

Heterolysis (chemistry) - Wikipedia

Fragmentation is a type of chemical dissociation, in which the removal of the electron from the molecule results in ionization. Removal of electrons from either sigma bond, pi bond or nonbonding orbitals causes the ionization. This can take place by a process of homolytic cleavage/ homolysis or heterolytic cleavage/ heterolysis of the bond. Relative bond energy and the ability to undergo favorable cyclic transition states affect the fragmentation process.

Heterolytic fission, also known as heterolysis, is a type of bond fission in which a covalent bond between two chemical species is broken in an unequal manner, resulting in the bond pair of electrons being retained by one of the chemical species (while the other species does not retain any of the

Two types of heterolytic fragmentations that have been reported in the literature but have received little theoretical attention are (1) extended fragmentations – heterolytic fragmentations that involve a chain of more than five atoms – and (2) divergent fragmentations – heterolytic fragmentations that involve the formation of two (or more) distinct products from a single substrate. 4 Extended fragmentations are unsurprisingly rare due to the complexity of orchestrating many bond ...

Four-membered heterocycles most often give fragments containing two ring atoms with their respective ligands. However, [3 + 1] fragmentation is well known, giving an atom (such as S) or stable species (such as SO 2) and often a three-membered ring. Examples are found in Schemes 4 and 5.

For most organic compounds the threshold energy for EI is about $\pu{10 eV}$ \$. After ionization of the molecule, the residual energy from the collision may cause the molecular ion to fragment into neutral pieces and smaller fragment ions. This fragmentation can be through either homolytic cleavage or heterolytic cleavage. The molecular ion is a radical cation, but the fragment ions may either be radical cations or carbocations, depending on the nature of the neutral fragment.

A type of dissociation where the electrons are removed from the molecule to form ions is called fragmentation. This fragmentation can be carried out by heterolytic or homolytic cleavage of the bond. Thus, the bond energy and its function to undergo cyclic transition states cause a major effect on the fragmentation process.
