Bending will be called as simple bending when it occurs because of beam self-load and external load. This type of bending is also known as ordinary bending and in this type of bending results both shear stress and normal stress in the beam. As shown below in the figure. Fig 3: Simple Bending Stress

Bending stress is a more specific type of normal stress. When a beam experiences load like that shown in

figure one the top fibers of the beam undergo a normal compressive stress. The stress at the horizontal plane of the neutral is zero. The bottom fibers of the beam undergo a normal tensile stress. It can be concluded therefore that the value of the bending stress will vary linearly with distance from the neutral axis.

The general formula for bending or normal stress on the section is given by: Given a particular beam section, it is obvious to see that the bending stress will be maximised by the distance from the neutral axis (y).

The formula to determine bending stress in a beam is: Where M is the moment at the desired location for analysis (from a moment diagram). c is the distance from the neutral axis to the outermost section (for symmetric cross sections this is half the overall height but for un-symmetric shapes the neutral axis is not at the midpoint).

 Normal stresses due to bending can be found for homogeneous materials having a plane of symmetry in the y axis that follow Hooke's law. Maximum Moment and Stress Distribution In a member of constant cross section, the maximum bending moment will govern the design of the section size when we know what

kind of normal stress is caused by it.

Beam Bending Stresses and Shear Stress

□ The internal bending moment , is the bending moment we represent in a bending moment diagram. The bending moment diagram shows how (and therefore stress) varies across a structure. If we know the state of longitudinal or normal stress due to bending at a given section in a structure we can work out the corresponding bending moment.

3.2 Beam bending If the load is applied in such a way that the structure deforms perpendicular to the axis of the structure, then such a deformation behavior is called bending. When a beam is loaded and subsequently bends, its longitudinal axis is deformed into a curve.

Deflected shape & Bending Moment
When a structural element is subjected to bending, it curves causing one side to stretch and the other to contract. This extension and contraction mobilise internal stresses (tensile and compressive, respectively) across the depth of the structural element, which when summed are referred to as the bending moment.
