Experimental Embryology

Experimental embryology identifies the stages of the determination of the material of rudimentary organs and tissues, the sources of formative or inductive influences, the role of synthesis of macromolecules in the processes of determination and differentiation, and the factors responsible for morphogenesis.

In this chapter, we will discuss three of the major research programs in experimental embryology. The first concerns how forces outside the embryo influence its development. The second concerns how forces within the embryo cause the differentiation of its cells. The third looks at how the cells order themselves into tissues and organs.

Experimental Embryology approaches to study regulative development and self-organisation in vitro. (a) Using embryonic stem cells (ESCs) from mouse embryos, aggregated in round-bottomed wells under defined conditions, the processes of multilineage cell fate differentiation, spatiotemporal organisation and axial morphology can be assessed. Because of their observed differentiation to three germ layers and axial organisation, these structures were termed 'gastruloids'.

Embryology is the branch of biology that studies the prenatal development of gametes, fertilization,

and development of embryos and fetuses. Additionally, embryology encompasses the study of congenital disorders that occur before birth, known as teratology. Early embryology was proposed by Marcello Malpighi, and known as preformationism, the theory that organisms develop from pre-existing miniature versions of themselves. Then Aristotle proposed the theory that is now accepted, epigenesis. Epige
