Background: The formulas of ionic compounds can be

determined by making sure their oxidation states (charges) add up to zero (neutral). This can be more easily visualized with puzzle pieces. An element with an oxidation state of +1 is represented by a puzzle piece with one tab jutting out (representing the electron it wants to lose). An element with an oxidation state of +2 is represented by a puzzle piece with two tabs jutting out, and so forth.

Forming an Ion. Ionic bonds are a class of chemical bonds that result from the exchange of one or more valence electrons from one atom,

typically a metal, to another, typically a nonmetal. This electron exchange results in an electrostatic attraction between the two atoms called an ionic bond.

An atom that loses one or more valence electrons to become a positively charged ion is known as a cation, while an atom that gains electrons and becomes negatively charged is known as an anion.

Ionic Bonds | Introduction to Chemistry

The Ionic Bond. When a highly electronegative atom and an electropositive one are bonded together, an electron is transferred from the electropositive atom to the electronegative atom to form a cation and an anion,

respectively. The cation, being a positively charged ion, is attracted to the negatively charged anion as described by Coulomb's law:

An ionic bond is actually the extreme case of a polar

covalent bond, the latter resulting from unequal sharing of electrons rather than complete electron transfer. Ionic bonds typically form when the difference in the electronegativities of the two atoms is great, while covalent bonds form when the electronegativities are similar. Compare covalent bond.

Introduction Ionic bonding is the complete transfer of valence electron (s) between atoms. It is a type of chemical bond that generates two oppositely charged

ions. In ionic bonds, the metal loses electrons to become a positively charged cation, whereas the nonmetal accepts those electrons to become a negatively charged anion.
