Mud Volcano S Formation Mechanism

This study investigated the factors controlling mud volcano activity and the triggering mechanisms of mud volcano eruptions on the southern margin of the Junggar Basin, NW China. The Baiyanggou, Aiqigou and Dushanzi mud volcanoes are all located along the Dushanzi Anticline, which belongs to the third anticline belt on the southern margin of the basin.

A mud volcano or mud dome is a landform created by the eruption of mud or slurries, water and gases. Several geological processes may cause the formation of mud volcanoes. Mud volcanoes are not true igneous volcanoes as they do not produce lava and are not necessarily driven by magmatic activity. The Earth continuously exudes a mud-like substance, which may sometimes be referred to as a "mud volcano".

The mud produced by mud volcanoes is mostly formed as hot water, which has been heated deep below the Earth's surface, begins to mix and blend with subterranean mineral deposits, thus creating the mud slurry exudate. This material is then forced upwards through a geological fault or fissure due to local subterranean pressure imbalances.

A mud volcano can appear hill or mound shaped, and differs from traditional igneous volcanoes because no lava or ashes are produced. Formation. Mud volcanoes can be man made or naturally occurring. Man made mud volcanoes can be triggered by mining or drilling for gas, which creates underground fault lines. When the soil deep within the Earth loosens in a process called decompaction, gases are created at a high rate.
