Introduction. The power of molecular genetics has recently returned the discipline of Developmental Biology to its original position at the forefront of biological research. The vertebrate eye was one of the classic embryologic models in the early 1900s. Within the last decade of the 20th century, a return to some of the old questions with the new approaches has put eye development back into the limelight.

During vertebrate development the eyes arise as evaginations from the developing diencephalon (FIG. 4; animated online).

Depressions called optic grooves form on each side of the rostral neural plate (FIG. 4b), and as the neural plate folds upwards and inwards (FIG. 4b,c), meeting and closing-over to form the neural tube, these growing regions balloon outwards (FIG. 4d) and are now termed optic vesicles.

that the two eye fields of vertebrates are generated from a single eye anlage, the generation of two eye fields from one was controversial for many decades. For example, Spemann (Spemann, 1938) favored the hypothesis that the two eyes are generated from two independent eye fields, while his major opponent at that time, Adelmann (1929), pioneered the notion that the two eyes are generated from a single eye anlage.

Regulation of vertebrate eye development by Rx genes

These results, together with the early expression of vertebrate Pax6 genes in the anterior neural plate (Grindley et al., 1995, Hirsch and Harris, 1997, Li et al., 1994, Loosli et al., 1998, Püschel et al., 1992, Walther and Gruss, 1991) has led to the suggestive 'master control gene hypothesis' for Pax6, as key

regulator of eye development conserved throughout bilaterian evolution (Gehring and Ikeo, 1999, Halder et al., 1995b, Quiring et al., 1994).

An eye on eye development - ScienceDirect

In most vertebrates and some molluscs, the eye works by allowing light to enter and project onto a light-sensitive panel of cells, known as the retina, at the rear of the eye. The cone cells (for colour) and the rod cells (for low-light contrasts) in the retina detect and convert light into neural signals for vision.

Eye - Wikipedia

The loss-of-function *ptch2* *tc294z* mutant displays coloboma, a structural defect in the eye caused by aberrant development of the optic fissure (Lee et al., 2008). Although the morphological features of the phenotype have been described in detail at stages after optic cup morphogenesis, the precise timing of the underlying cellular defects is unknown.

Hedgehog signaling regulates cell motility ... - Development

Morphological development of the vertebrate eye begins with the formation of an outpouching of the diencephalon called the optic vesicle (Fig. 1 A). The optic vesicle subsequently contacts the head ectoderm (Fig. 1 B) and signals the induction of a pseudostratified thickening of the ectoderm called the lens placode (Fig. 1 C).

In *Drosophila*, as well as in vertebrates, Pax6 is both essential for eye differentiation, and sufficient to induce eye development in certain regions of the body (Chow et al., 1999; Halder et al., 1995; Hill et al., 1991; Quiring et al., 1994). This functional conservation of a specific transcription factor implies a common evolutionary origin ...
