Schematic Raw Water Cooled Engine
Two streams of water are required in all
raw-water cooled engines, one to effect
cooling, regulated by the thermostat, the
other, known as the bypass, flowing at
all times to cool the exhaust system. On
some engines, such as the Bukh, there is
an external Y-branch. On the Volvo Penta
the branch occurs inside the cylinder
head.

The water is kept continuously in motion by a centrifugal water pump which is driven by a V-belt from the pulley on the engine crankshaft. After passing through the engine jackets in the block and

cylinder heads. The water is passing through the radiator. In the radiator, the water is cooled by air drawn through the radiator by a fan.

Types of Cooling System In Engine | Working and Advantages

Water cooled Engine Construction: Water jackets are carved out inside the cylinder head and block. It helps the water to reach the hottest surfaces located within the engine and remove the heat effectively. More the surface area comes in contact with water, it dissipates more heat. Also, the water-cooled engine uses a water pump to improve the rate of water flow.

The raw water pump on the engine flows sea water through the inside of the smaller tubes and makes passes back and forth across the unit while removing the heat from the engine before finally exiting and flowing out the exhaust system.

Run the engine until water stops coming out of the exhaust(max,a couple of minutes)There may be a water trap on the exhaust(This stops water running back into the engine)If so,it will usually have a drain on the bottom.Make sure that the direct cooling system has at

An initial fill and flush is recommended, although not necessary for a brand new engine. This fill is to check the system for leaks and to help remove any sediment that remains in spite of the cold-water flush that was performed as part of the installation. For engines that have been previously cooled with raw-water, the flushing is critical.

Marine Diesel Engines, Part 1 – Overview of the Raw Water System. Understanding the raw water cooling system of your boat's diesel engine will help you keep her running cool. Keeping your marine diesel engine running cool is explained here: From the raw water inlet through the seacock, the strainer, and the heat exchanger and then out the the wet exhaust, water from outside the boat circulates to keep the engine coolant cool.

Marine Diesel Engines, Part 1 | Raw Water Cooling System

The raw water will be used with your Engine Oil and Power Steering Coolers as they will not be part of the closed circulating system. From Here the raw water will be passed into the heat exchanger tank and be pumped through many small tubes where it will exchange heat from the circulating systems water. The raw water then exits the heat

exchanger to go directly into the risers and then exit the boat.

Marine Closed Cooling Systems - cpperformance.com

The raw water is pumped through a bundle of small tubes in a chamber filled with the hot engine coolant. The tubes are cooled by the colder raw water the allowing the tubes to absorb the heat of the engine coolant. To function correctly, a heat exchanger must be carefully matched to your boat's engine.
