Intensity Distribution Of The Interference

Interference depends on the relative phase of the two waves. It also depends on the path difference between them. The resultant intensity at a point is proportional to the square of the resultant electric field at that point. $I \propto E^2$

For constructive interference, intensity will be maximum, $I_R = (\sqrt{I_1} + \sqrt{I_2})^2 = 4I_0$. For destructive interference, the intensity is minimum and $I_R = (\sqrt{I_1} - \sqrt{I_2})^2 = 0$ if the light waves have equal intensity.

The amplitude of the electromagnetic wave is correspondingly diminished to $1/N$ of the wave at the principal maxima, and the light intensity, being proportional to the square of the wave amplitude, is diminished to $1/N^2$ of the intensity compared to the principal maxima. Single Slit Diffraction Intensity. Under the Fraunhofer conditions, the wave arrives at the single slit as a plane wave. Divided into segments, each of which can be regarded as a point source, the amplitudes of the segments will have a constant phase displacement from each other, and will form segments of a circular arc when added as vectors.

Single Slit Diffraction Intensity

Single slit diffraction factor oscillates with lesser frequency and modulates the higher frequency multi-slit interference factor, which determines maxima and minima of intensity. Central peak of intensity at $\theta=0$ in diffraction grating with N slits is N^2 times the central intensity from individual slit

Since it is interference that modifies the spectral contents, the spectral intensity distribution inside the resonator would be the same as the incident spectral intensity distribution, and no resonance enhancement would occur inside the resonator.

Fabry-Pérot interferometer - Wikipedia

Diffraction is the phenomenon of bending of light around the corners of small apertures or obstacles and its spreading into the region of the geometrical shadow. The intensity distribution wave for diffraction is shown in the above figure. In interference, all bright fringes are of same intensity. In diffraction, the intensity of bright fringes decreases with the increase in distance from the central bright fringe.

If the slit width a is varied, the intensity distribution changes, as illustrated in Figure 4.3.4. The central peak is distributed over the region from $\sin\theta = -\lambda/a$ to $\sin\theta = +\lambda/a$. For small θ , this corresponds to an angular width $\Delta\theta \approx 2\lambda/a$.

4.3: Intensity in Single-Slit Diffraction - Physics LibreTexts

This Demonstration shows the two-dimensional intensity distribution generated by the interference of two coherent wave sources. The distance between the two sources, as well as their wavelength, can be varied. Lines of constructive and destructive interference can be displayed, hyperbolic in shape. The locator on the diffraction pattern can be moved to show the path difference as an integer or half-integer multiple of the wavelength.

The intensity of the maximum is then. $I_0 = \frac{1}{2} \epsilon_0 c (N \Delta E_0)^2 = \frac{1}{2} \mu_0 c (N \Delta E_0)^2$, $I_0 = \frac{1}{2} \epsilon_0 c (N \Delta E_0)^2 = \frac{1}{2} \mu_0 c (N \Delta E_0)^2$, where. $\epsilon_0 = 1/\mu_0 c^2$. $\epsilon_0 = 1/\mu_0 c^2$. The phasor diagrams for the first two zeros of the diffraction pattern are shown in parts (b) and (d) of the figure.
