Preoperative Embolization Of The Head

Preoperative Embolization. Many of the tumors that occur in the head, neck, and spine have a large blood supply. This can make surgical removal of these tumors difficult and risky. These tumors include meningiomas (tumors of the covering of the brain), paragangliomas or glomus tumors (tumors associated with nerves of the head and neck), juvenile nasopharyngeal angiofibromas (tumors of the nose that occur in young males), head and neck cancers, and tumors of the bones of the spine (vertebrae).

Preoperative Embolization of the Head and Neck

The histologic changes induced by embolization in paragangliomas of the head and neck may be classified in four stages. Histologically, the best time for surgery is within 8 days from embolization; surgery performed more than 8 days following embolization, however, is not compromised by revascularization.

The first descriptions of preoperative embolization of head and neck tumors were in the early 1970s for the treatment of juvenile nasal angiofibroma and glomus jugulare tumors (Roberson et al 1972; Hekster et al 1973). Since then, preoperative embolization has become an important adjunct in the management of hypervascularized tumors and is standard practice at the authors' institution.
