The overall enthalpy change that accompanies the formation of a solution, ΔH soln, is the sum of the enthalpy change for breaking the intermolecular interactions in both the solvent and the solute and the enthalpy change for the formation of new solute-solvent interactions. Exothermic (ΔH soln < 0) processes favor solution formation. In addition, the change in entropy, the degree of disorder of the system, must be considered when predicting whether a solution will form.

spontaneous solution formation - usually exothermic. energy decrease >> reaction starts spontaneously. entropy/disorder increase >> reaction starts spontaneously (even if endothermic) molecules unrestrained >> spontaneous mixing occurs.

Solution Formation | CourseNotes

There is an entropy change associated with the formation of a solution, an increase in entropy (randomness) that thermodynamically favors the solution over the two original states. If the other energetics of dissolution are favorable, this increase in entropy means that the conditions for solubility will always be met.

The enthalpy of solution is most often expressed in kJ / mol at constant temperature. The energy change can be regarded as being made of three

parts, the endothermic breaking of bonds within the solute and within the solvent, and the formation of attractions between the solute and the solvent. An ideal solution has a null enthalpy of mixing.
