Dna Rna And Proteins Study

The central dogma of molecular biology states that genetic information flows

from DNA to RNA and then to protein.

The process of converting DNA to RNA is called transcription. A separate process, called translation, converts the information in RNA to the specific sequence of amino acids in proteins.

DNA, RNA, and Protein

DNA in the cell nucleus carries a genetic code, which consists of sequences of adenine (A), thymine (T), guanine (G), and cytosine (C) (Figure 1). RNA, which contains uracil (U) instead of thymine, carries the code to protein-making sites in the cell. To make RNA, DNA pairs its bases with those of the “free” nucleotides (Figure 2).

In biology, epigenetics is the study of heritable phenotype changes that do not involve alterations in the DNA sequence. The Greek prefix epi-(ἐπι-"over, outside of, around") in epigenetics implies features that are "on top of" or "in addition to" the traditional genetic basis for inheritance. Epigenetics most often involves changes that affect gene activity and expression, but the term ...
