The linear theory of stability is unable to give a correct answer since its analysis is limited to first-order terms and its results are not significant when $\exp(\omega t)$ becomes significant. A correct answer is given by the bifurcation theory. The correct solution obtained by numerical integration shows that the system tends towards a limit cycle i.e. to Prigogine's dissipative structure.

The aim of this chapter is to introduce tools from bifurcation theory which will be necessary in the following sections for the study of neural field equations (NFE) set in the primary visual cortex. In a first step, we deal with elementary bifurcations in low dimensions such as saddle-node, transcritical, pitchfork and Hopf bifurcations.

A much simpler way of thinking about it is that stability describes the nature of one system, whereas bifurcation describes the nature of a family of systems.

What is the difference between bifurcation and stability?

A moderate mathematical background is assumed, and whenever possible, only elementary mathematical tools are used. This new edition preserves the structure of the first edition, while updating the context to incorporate recent theoretical developments, in particular, new and improved numerical methods for bifurcation analysis.

Bifurcation theory is the mathematical study of changes in the qualitative or topological structure of a given family, such as the integral curves of a family of vector fields, and the solutions of a family of differential equations. Most commonly applied to the mathematical study of dynamical systems, a bifurcation occurs when a small smooth change made to the parameter values of a

system causes a sudden 'qualitative' or topological change in its behavior. Bifurcations occur in both continuous
