In this module, you will learn how to use multispectral imagery, a type of remote sensing data, to better understand changes in the landscape and how to calculate NDVI using various

multispectral datasets You will also review spectral remote sensing as a passive type of remote sensing and how to work with space-borne vs airborne remote sensing data in R. Additionally, we will cover raster stacks in R, plotting multi-band composite images, calculating vegetation indices and creating functions ...

Spectral fingerprints An interesting feature-extraction technique for hyperspectral data was developed in a series of papers by Piech and Piech (1987, 1989). The basic concept is to locate the local points of inflection (maximum slope) in the spectral curve using scale-space filtering (Chapter 6).

Each pixel is recorded at 224 channels ranging from 380 nm to 2500 nm. The spectral resolution is up to 9.46nm. Since this hyperspectral image is too complex to get the ground truth, we consider a subimage of 100 x 100 pixels. The first pixel starts from the (105,269)-th pixel in the original image.

Indian Pines. This scene was gathered by AVIRIS sensor over the Indian Pines test site in North-western Indiana and consists of 145\times145 pixels and 224 spectral reflectance bands in the wavelength range 0.4–2.5 $10^{(-6)}$ meters. This scene is a subset of a larger one. The Indian Pines scene contains two-thirds agriculture, and one-third forest or other natural perennial vegetation.

This correspondence paper studies face recognition by using hyperspectral imagery in the visible light bands. The spectral measurements over the visible spectrum have different discriminatory information for the task of face identification, and it is found that the absorption bands related to hemoglobin

are more discriminative than the other bands.
