In a physics equation, given a constant acceleration and the change in velocity of an object, you can figure out both the time involved and the distance traveled. For instance, imagine you're a drag racer. Your acceleration is 26.6 meters per second², and your final speed is 146.3 meters per second. Now find the total distance traveled. Got you, huh?

Or suppose that at one time during a shopping trip your instantaneous velocity is 40 km/h due north. Your instantaneous speed at that instant would be 40 km/h—the same magnitude but without a direction. Average speed, however, is very different from average velocity. Average speed is the distance traveled divided by elapsed time.

The distance-time graph for a uniformly accelerated motion looks as shown in the graph above, consider how the distance is changing exponentially indicating that the velocity is changing at a constant rate or there is constant acceleration. But in the velocity time graph as velocity changes at a constant rate with respect to time in uniformly accelerating motion, the graph would be a straight line with its slope indicating the amount of acceleration.

To solve for distance use the formula for distance $d = st$, or distance equals speed times time. distance = speed x time Rate and speed are similar since they both represent some distance per unit time like miles per hour or kilometers per hour. If rate r is the same as speed s , $r = s = d/t$.

Moreover direct integration is not the right thing because acceleration is not constant. Instead, what you can do is fit a line (linear regression) between time and velocity. The slope of the

line is the acceleration. You can then use $d = 0.5 * \text{acceleration} * ((\text{delta_time})^2)$ to get the distance traveled here for each time interval.
