Power plants strip CO 2 from flue emissions today by bubbling flue gases through organic amines in water, which bind and extract the carbon dioxide. The liquid is then heated to 120-150 C (250-300 F) to release the CO 2 gas, after which the liquids are reused. The entire process consumes about 30% of the power generated.

CO 2 capture is a process with high energy consumption due to the huge volumetric flow rate of the flue gas and low concentration of CO2 (approximately 13%) in conventional coal-fired power plants. Implementing CO2 capture would lower the thermal efficiencies of coal-fired power plants by approximately 9-13%.

In addition to these processes, the parasitic loads imposed by carbon capture on power plants will reduce their efficiency and thus require more water for cooling the plant. Groundwater contamination due to CO 2 leakage during geologic sequestration is an additional concern when adapting CCS into power plants. Imposing such constraints on the quantity and quality of freshwater resources will influence decisions on the types of energy facilities and threaten the sustainability of water systems.
