Nuclear Magnetic Resonance. NMR is based on the behavior of a sample placed in an electromagnet and irradiated with radiofrequency waves: 60 –900 MHz ($\lambda \approx 0.5$ m) The magnet is typically large, strong, \$\$\$, and delivers a stable, uniform field –required for the best NMR data. A transceiver antenna, called the NMR probe, is inserted into the center bore of the magnet, and the sample is placed inside the probe.

NMR uses a large magnet (Magnetic) to probe the intrinsic spin properties of atomic nuclei. Like all spectroscopies, NMR uses a component of electromagnetic radiation (radio frequency waves) to promote transitions between nuclear energy levels (Resonance). Most chemists use NMR for structure determination of small molecules.

NMR spectroscopy is the most common and comprehensive technique for studying the structure of organic molecules. In a broad sense, it still works by the same principle as other spectroscopies, and that is the interaction of the molecule with certain type of energy to produce different energy states and deduce information based on these differences. There is, however, a lot more information you can get from an NMR spectrum than what we have seen in the IR spectroscopy and Mass Spectrometry.
